# Overview of the content

**Polynomial interpolation** is an important building block of numerical analysis.

We try to fit a polynomial  $P$  of degree  $\leq n$  that exactly pass by  $n + 1$  given points

$$y_i = P(x_i), \quad i \in \{0, n\}.$$

It is a special case of **approximation**: find a simpler function  $P$  (we focus on polynomials) that is the closest to  $f$  with respect to some **distance**

- We can study the **interpolation error**, where we have more liberty to choose the  $x_i$
- We do not need  $P$  to pass through  $x_i$ , but only capture the main trend of  $f$ : **least squares**

If we have a lot of data  $(x_i, y_i)$ ,  $i \in \{0, m\}$  with  $m \gg n$ , we can try to **fit the data** to a polynomial  $P$  of lower degree  $n$ , we talk about **discrete least squares**.

## Polynomial evaluation

Let  $P$  be a polynomial of degree  $n$

$$P(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_2 x^2 + a_1 x + a_0,$$

that we want to evaluate at a point  $x = \xi$

- one algorithm consists in computing each product  $a_n \xi^n$  and next summing.
- but this technique is generally not used
  - because of the errors that it generates (cf last week exercise)
  - the number of elementary operations is too large, most particularly when  $n \gg 1$ :  $n(n+1)/2$  multiplications and  $n$  additions  $\rightarrow \mathcal{O}(n^2)$  operations.
- the **Hörner algorithm** is generally preferred

## Polynomial evaluation

Let  $P$  a polynomial of degree  $n$

$$P(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_2 x^2 + a_1 x + a_0,$$

that we want to evaluate at a point  $x = \xi$

## Hörner algorithm

The Hörner algorithm is based on the following factorization

$$P(x) = a_0 + x(a_1 + x(a_2 + x(a_3 + \dots x(a_{n-2} + x(a_{n-1} + xa_n))))))$$

This algorithm requires  $n$  additions and  $n$  multiplications  $\rightarrow \mathcal{O}(n)$  operations

It has a convenient recursive form

## Lagrange interpolation

### The interpolation problem

Let  $(y_i, x_i)$  be  $n + 1$  distinct points  $x_0, x_1, \dots, x_n$  and  $y_0, y_1, \dots, y_n$  on the interval  $[a, b]$ .  
The goal is to build a polynomial  $P$  of degree less or equal to  $n$  such that

$$P(x_i) = y_i \quad \forall i = 0, 1, \dots, n$$

## Theorem

There exists one and only one polynomial  $P_n$  of degree less or equal to  $n$  satisfying

$$P_n(x_i) = y_i \quad \forall i = 0, 1, \dots, n$$

which writes

$$P_n(x) = \sum_{i=0}^n y_i L_i(x) \quad \text{with} \quad L_i(x) = \prod_{k=0, k \neq i}^n \frac{(x - x_k)}{(x_i - x_k)}.$$

- This polynomial  $P_n$  is called **Lagrange interpolation polynomial** at the points  $x_0, x_1, \dots, x_n$ .
- The polynomials  $L_i(x)$  are the Lagrange basis functions associated to the points  $x_i$ .

## Proof

- Existence

The polynomial function  $P_n$  is a polynomial of degree  $n$ . Since  $L_i(x_j) = \delta_{ij}$ , it satisfies

$$P_n(x_i) = y_i \quad \forall i = 0, 1, \dots, n$$

## Proof

- Existence

The polynomial function  $P_n$  is a polynomial of degree  $n$ . Since  $L_i(x_j) = \delta_{ij}$ , it satisfies

$$P_n(x_i) = y_i \quad \forall i = 0, 1, \dots, n$$

- Uniqueness

Let  $Q$  be another polynomial function solution to the problem. Then  $\forall i = 0, 1, \dots, n$

$$Q(x_i) - P(x_i) = 0 \quad \forall i = 0, 1, \dots, n.$$

Therefore  $Q - P$  is a polynomial function of degree less or equal to  $n$  which is zero at  $n + 1$  points. As a consequence, this polynomial is identically zero.

## Example

With two points  $n = 1$

$$P_1(x) = y_0 \frac{(x - x_1)}{(x_0 - x_1)} + y_1 \frac{(x - x_0)}{(x_1 - x_0)}$$

which can also be written

$$P_1(x) = y_0 + \frac{y_1 - y_0}{x_1 - x_0} (x - x_0).$$

## Example

Find the interpolating polynomial for

$$(x_0, x_1, x_2) = (0, 2, 3), \quad (y_0, y_1, y_2) = (1, 5, -2)$$

**Step 1:** look for the 2nd order Lagrange basis  $(L_0, L_1, L_2)$  such as  $L_i(x_j) = \delta_{ij}$ .

**Step 2:** use the theorem to find  $P_2$  by linear combination

Review: stable evaluation of a polynomial

Lagrange interpolation

**Newton form of the interpolant**

Error in interpolation

## 3. Polynomial approximation theory

Least squares problem

Orthogonal polynomials

## 4. Discrete least squares - polynomial data fit

## Remark

Computing  $P_n(x) = \sum_{i=0}^n y_i L_i(x)$  requires too much elementary evaluations.

## Newton form of the interpolation polynomial

We prefer to use the Newton formula which consists in writing the interpolation polynomial  $P_n$  at points  $x_0, x_1, \dots, x_n$  under the form

$$P_n(x) = a_0 + a_1(x - x_0) + \dots + a_n(x - x_0)(x - x_1) \dots (x - x_{n-1})$$

## Advantages

- we can use the stable Hörner algorithm to evaluate this polynomial
- If we know  $P_{n-1}$ , it is sufficient to compute  $a_n$  to determine  $P_n$

$$P_n(x) = P_{n-1}(x) + a_n(x - x_0)(x - x_1) \dots (x - x_{n-1})$$

(this is useful most particularly if one point is added!)

## Newton interpolation formula - Divided differences

The coefficients  $a_n$  can be expressed explicitly by *divided differences*

$$P_n(x) = \sum_{j=0}^n \left( a_j \prod_{i=0}^{j-1} (x - x_i) \right), \quad a_j = f[x_0, x_1, \dots, x_j]$$

where  $f[.]$  are the divided differences of  $f$  such as

$$f[x_0, x_1, \dots, x_j] = \frac{f[x_1, \dots, x_j] - f[x_0, \dots, x_{j-1}]}{x_j - x_0}.$$

The recursion begins with  $f[x_j] = f(x_j)$ ,  $\forall j \in \{0, n\}$  (see implementation exercise)

### Remark

Although the interpolating polynomial is unique, it can be written in different forms

## Error measure for polynomial interpolation

Since one of the goals of the interpolation is to replace the evaluation of  $f(x)$  by  $P_n(x)$ , an important point is to measure the error

$$E_n(x) = f(x) - P_n(x), \quad x \in [a, b]$$

Can we approach a continuous function  $f$  by its Lagrange polynomial interpolant ?

If  $f$  has  $n + 1$  bounded derivatives,

$$E_n(x) = \frac{f^{(n+1)}(\xi_x)}{(n+1)!} \prod_{i=0}^n (x - x_i), \quad \xi_x \in [a, b]$$

### Example

- Sinusoidal function on  $[-\pi, \pi]$ , equidistant points
- $x \mapsto 1/(1+x^2)$  on  $[-a, a]$ , equidistant points

## Error measure for the polynomial interpolation

### Theorem

Let  $f : [a, b] \rightarrow \mathbb{R}$ ,  $n + 1$  times continuously differentiable and  $P_n$  the Lagrange interpolation polynomial at points  $x_0, x_1, \dots, x_n$  in  $[a, b]$ . Then

$$|f(x) - P_n(x)| \leq \frac{M_{n+1}}{(n+1)!} |\pi_n(x)|$$

where

$$M_{n+1} = \max_{a \leq x \leq b} |f^{(n+1)}(x)|$$

and

$$\pi_n(x) = \prod_{i=0}^n (x - x_i).$$

## Example

$f(x) = \sin(x)$  for  $x \in [a, b]$

- we have  $M_{n+1} \leq 1$
- we also can easily obtain the upper bound  $|\pi_n(x)| \leq (b-a)^{n+1}$  (for any choice of the  $n+1$  points  $x_i$ )
- then

$$\forall x \in [a, b], \quad |f(x) - P_n(x)| \leq \frac{(b-a)^{n+1}}{(n+1)!}$$

- and, consequently

$$\lim_{n \rightarrow \infty} |f(x) - P_n(x)| = 0$$

## Example

$f(x) = 1/(1 + x^2)$  for  $x \in [-a, a]$

- if the points  $x_i$  are equispaced in  $[-a, a]$ , we can show that

$$\max_{-a \leq x \leq a} |E_n(x)| < C \frac{e^{-n}}{\sqrt{n \log n}} (2a)^{n+1}$$

- so if  $2a < e$ ,  $E_n(x)$  converges towards 0 with  $n$ .
- in our simulation  $a = 5$  and in this case, the upper bound tends to infinity. We cannot say anything about  $E_n(x)$ .
- our computation lets to think that  $E_n$  does not tends to 0
- and  $\max_{|x| \leq 5} |E_n(x)|$  did not converge towards 0 (**Runge phenomena**)

## Choice of the interpolation points

- the error estimates of the theorem shows that the error depends on
  - the  $(n + 1)$ -th derivative of  $f$
  - the maximum of the function  $\pi_n$ , which only depends on the  $x_i$
- We can try to minimize  $\max_{a \leq x \leq b} |\pi_n(x)|$  by a better choice of the points  $x_i$
- choosing equally distributed points is far from being optimal!
- the optimal choice is obtained by the **Chebyshev points**

$$x_i = \frac{a + b}{2} + \frac{b - a}{2} \cos \left( \frac{(2i + 1)\pi}{2n + 2} \right), i = 0, 1, \dots, n$$

Another way to avoid Runge phenomena is by **piecewise interpolation**

- linear, quadratic, spline, nearest neighbourhood, etc.

# Least squares problem

## Continuous polynomial least squares approximation

Let  $f$  be a continuous function in  $[a, b]$

**Goal:** find  $\min_{P \in \mathbb{R}_n[X]} \|f - P\|_{L_2}^2$ , with  $P = \sum_{i=0}^N a_i \phi_i(x)$ ,  $\{\phi_i\}$  a basis of  $\mathbb{R}_n[X]$ .

To do so we study the error  $\langle f - P, f - P \rangle_{L_2}$

$$\mathcal{E}(a_0, \dots, a_n) = \int_a^b \left[ f(x) - \sum_{i=0}^N a_i \phi_i(x) \right]^2 dx$$

and solve  $\frac{\partial \mathcal{E}}{\partial a_j} = 0$ ,  $\forall j \in \{0, n\}$

We obtain a linear system for the  $(a_j)_{j \in \{0, n\}}$

$$\langle f, \phi_j \rangle = \sum_{i=0}^n a_i \langle \phi_i, \phi_j \rangle$$

# Outline

## 1. Overview

## 2. Polynomial interpolation

Review: stable evaluation of a polynomial

Lagrange interpolation

Newton form of the interpolant

Error in interpolation

## 3. Polynomial approximation theory

Least squares problem

Orthogonal polynomials

## 4. Discrete least squares - polynomial data fit

### Definition

A sequence of orthogonal polynomials (finite or infinite)  $\phi_0(x), \phi_1(x), \dots$  is such that

$\phi_i$  is of degree  $i$

$$\langle \phi_i, \phi_j \rangle = 0, \quad \text{if } i \neq j.$$

We study the sequences of orthogonal polynomials for a scalar product like

$$\langle \phi, \psi \rangle_{L_2} = \int_a^b \phi(x)\psi(x)w(x)dx$$

where  $w$  (= weight) is a strictly positive continuous function on  $]a, b[$

**Remark:** orthogonal polynomials ( $w = 1$ ) solves the least squares system:  $a_j = \frac{\langle f, \phi_j \rangle}{\langle \phi_j, \phi_j \rangle}$

## Properties of orthogonal polynomials

Let  $(\phi_n)$  be a sequence of orthogonal polynomials; then

- Any polynomial  $P$  of degree less or equal to  $k$  writes in a unique way like

$$P(x) = d_0\phi_0(x) + d_1\phi_1(x) + \dots + d_k\phi_k(x) \quad \text{with } d_i = \frac{\langle \phi_i, P \rangle}{\langle \phi_i, \phi_i \rangle}$$

- If  $P$  is of degree  $< k$ , then  $\langle P, \phi_k \rangle = 0$
- If  $A_i$  designates the coefficient of the term of highest degree of  $\phi_i$ , then we have the three terms short recurrence

$$\widehat{\phi}_{i+1}(x) = (x - B_i)\widehat{\phi}_i(x) - C_i\widehat{\phi}_{i-1}(x) \quad \text{where } \widehat{\phi}_i(x) := \frac{\phi_i(x)}{A_i} \quad (\text{normalized polyn.})$$

$$B_i = \frac{\langle x\widehat{\phi}_i(x), \widehat{\phi}_i(x) \rangle}{\langle \widehat{\phi}_i(x), \widehat{\phi}_i(x) \rangle}, \quad C_i = \frac{\langle \widehat{\phi}_i(x), \widehat{\phi}_i(x) \rangle}{\langle \widehat{\phi}_i(x), \widehat{\phi}_{i-1}(x) \rangle}.$$

- $\phi_i$  has exactly  $i$  real-valued distinct zeroes

## Standard examples of orthogonal polynomials

### Jacobi polynomials

$$[a, b] = [-1, 1] \quad \text{and} \quad w(x) = (1-x)^\alpha(1+x)^\beta$$

with  $\alpha > -1$  and  $\beta > -1$

- $\alpha = \beta = 0$  : Legendre polynomials.

$$(n+1)L_{n+1}(x) = (2n+1)xL_n(x) - nL_{n-1}(x).$$

- $\alpha = \beta = -\frac{1}{2}$  : First-kind Chebyshev polynomials defined by

$$T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x).$$

- $\alpha = \beta = \frac{1}{2}$  : Second-kind Chebyshev polynomials

## Standard examples of orthogonal polynomials

### Laguerre polynomials

$$]a, b[ = [0, +\infty[ \quad \text{and} \quad w(x) = e^{-x}$$

The recursive relation writes:

$$\mathcal{L}_{n+1}(x) = -\frac{1}{n+1}(x - 2n - 1)\mathcal{L}_n(x) - n\mathcal{L}_{n-1}(x)$$

### Hermite polynomials

$$]a, b[ = ]-\infty, +\infty[ \quad \text{and} \quad w(x) = e^{-x^2}$$

The recursive relation writes:

$$H_{n+1}(x) = 2xH_n(x) - 2nH_{n-1}(x)$$

## Orthogonal polynomials - Best least squares approximation

### Theorem

Let  $f : [a, b] \rightarrow \mathbb{R}$  be such that  $\langle f, f \rangle < \infty$ . Then, for any  $1 \leq k \leq (N - 1)$ , if  $\phi_0, \phi_1, \dots, \phi_k$  is a sequence of orthogonal polynomials for the inner product  $\langle \cdot, \cdot \rangle$ , there is a unique polynomial function  $P$  of the form

$$P(x) = a_0\phi_0(x) + a_1\phi_1(x) + \dots + a_k\phi_k(x)$$

minimizing  $\langle f - P, f - P \rangle$ . The coefficients are given by

$$a_i = \frac{\langle \phi_i, f \rangle}{\langle \phi_i, \phi_i \rangle}, \quad i = 0, \dots, k.$$

### Example

Find the polynomial  $P$  of degree less or equal to 3 that minimizes

$$\int_{-1}^1 (e^x - P(x))^2 dx.$$

### Legendre polynomials in $[-1, 1]$

We use the basis of Legendre polynomials

$$L_0(x) = 1, \quad L_1(x) = x, \quad L_2(x) = \frac{3}{2} \left( x^2 - \frac{1}{3} \right), \quad L_3(x) = \frac{5}{2} \left( x^3 - \frac{3}{5}x \right).$$

## Determining the coefficients

For  $f(x) = e^x$ , we compute

$$\langle f, L_0 \rangle = \int_{-1}^1 e^x dx = e - \frac{1}{e} \quad \langle f, L_1 \rangle = \int_{-1}^1 x e^x dx = \frac{2}{e}$$

$$\langle f, L_2 \rangle = \frac{3}{2} \int_{-1}^1 e^x \left( x^2 - \frac{1}{3} \right) dx = e - \frac{7}{e} \quad \langle f, L_3 \rangle = \frac{5}{2} \int_{-1}^1 e^x \left( x^3 - \frac{3}{5} \right) dx = -5e + \frac{37}{e}.$$

In addition, we have:  $\langle L_i, L_j \rangle = \frac{2}{2^{i+1}}$ . Hence, we deduce the polynomial solution

$$P(x) = 1.175201194L_0(x) + 1.10363824L_1(x) + 0.3578143506L_2(x) + 0.07045563367L_3(x).$$

## Remarks

- orthogonal polynomials have various mathematical properties
- they are useful for developing highly accurate numerical methods (numerical integration, spectral methods, etc.)
- beyond polynomials: trigonometric basis  $(1, \cos(kx), \sin(kx))_{k>0}$  leads to Fourier series

# Outline

## 1. Overview

## 2. Polynomial interpolation

Review: stable evaluation of a polynomial

Lagrange interpolation

Newton form of the interpolant

Error in interpolation

## 3. Polynomial approximation theory

Least squares problem

Orthogonal polynomials

## 4. Discrete least squares - polynomial data fit

## Polynomial least square data fit

We are given a set of data  $(y_i)_{1 \leq i \leq m}$ , with possibly  $m \gg n$ , and want to solve the minimization problem

$$\min_c \sum_{i=1}^m (y_i - \hat{f}(x_i, c))^2$$

where the unknowns are the coefficients  $(c_j)_{1 \leq j \leq n}$  from a polynomial basis

$$\hat{f}(x, c) = \sum_{j=1}^n c_j \phi_j(x)$$

We try the monomial basis such that  $\phi_j(x) = x^{(j-1)}$ ,  $j \in [1, n]$ . The polynomial degree  $n$  should be large enough to contain information but not too large to avoid spurious noise.

### Example

Linear regression with  $\hat{f}(x, c) = c_1 x + c_2$

## Remarks

- if  $m = n$ , we have interpolation
- we study the discrete analogue of the continuous least square problem
- there are other choices to measure the error, based on different distances
  - the maximum norm:

$$\max_{0 \leq i \leq m} |y_i - \sum_{1 \leq j \leq n} c_j \phi_j(x_i)|.$$

- the absolute value norm:

$$\sum_{0 \leq i \leq m} |y_i - \sum_{1 \leq j \leq n} c_j \phi_j(x_i)|.$$

This will lead different solutions for the  $(c_j)_{1 \leq j \leq n}$ . We focus on the Euclidean distance because it leads a linear problem.

The problem for the  $p$ -norm writes

$$\min_c \|Ac - y\|_p^2$$

with  $(A_{ij}) = \phi_j(x_i)$  is a  $m \times n$  matrix, sampling the data on the chosen polynomial basis.

## Normal equations

$$E(c) = \sum_{0 \leq i \leq m} (y_i - \sum_{1 \leq j \leq n} c_j \phi_j(x_i))^2.$$

with  $c = (c_1, c_2, \dots, c_n)$ . if  $E$  has a minimum in  $c$ , then

$$\frac{\partial E}{\partial c_i}(c) = 0, \quad \forall i = 1, \dots, n$$

which writes

$$2 \sum_{0 \leq i \leq m} \phi_j(x_i) (y_i - (c_1 \phi_1(x_i) + \dots + c_n \phi_n(x_i))) = 0, \quad \forall j = 1, \dots, n$$

which are called the **normal equations**. In matrix form, we have

$$2A^T(Ac - y) = 0 \Leftrightarrow A^T Ac = A^T y$$

## Remarks

- the matrix  $A^T A$  is of size  $n \times n$
- if  $A$  has full column rank,  $A^T A$  is symmetric positive definite and we have a unique minimizer
- $A$  is usually badly conditioned
- The number of data  $m$  might be very large and/or noisy
- The method is not restricted to a polynomial basis
- There are various ways to solve the normal equation (see Chapter on linear systems)

# Summary of the contents

## **Polynomial interpolation :**

1. Global polynomial interpolation (Lagrange interpolant)  
Error study: Runge phenomena, Chebychev points
2. Local interpolation follows the same ideas (see exercises)  
Higher degree local interpolation requires more data (new point, derivative(s), ...)  
⇒ more unknowns to be solved

## **Approximation theory :**

1. Orthogonal polynomials are an important building block for advanced numerical methods
2. Discrete least-squares is an example of convex optimization, and is a starting point for advanced topics (non-linearity, machine learning, , etc.)
